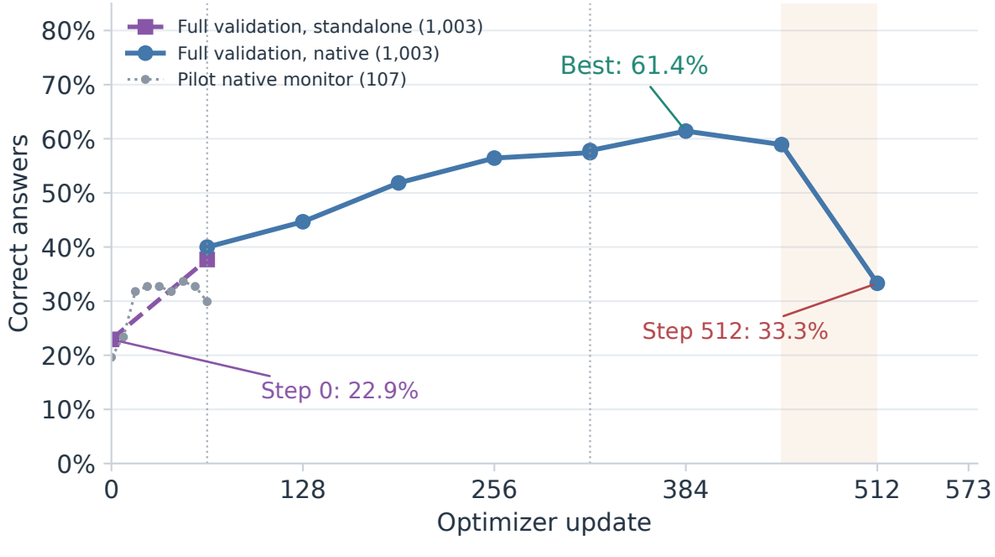
Snowball RL: the full history from step 0 to 573

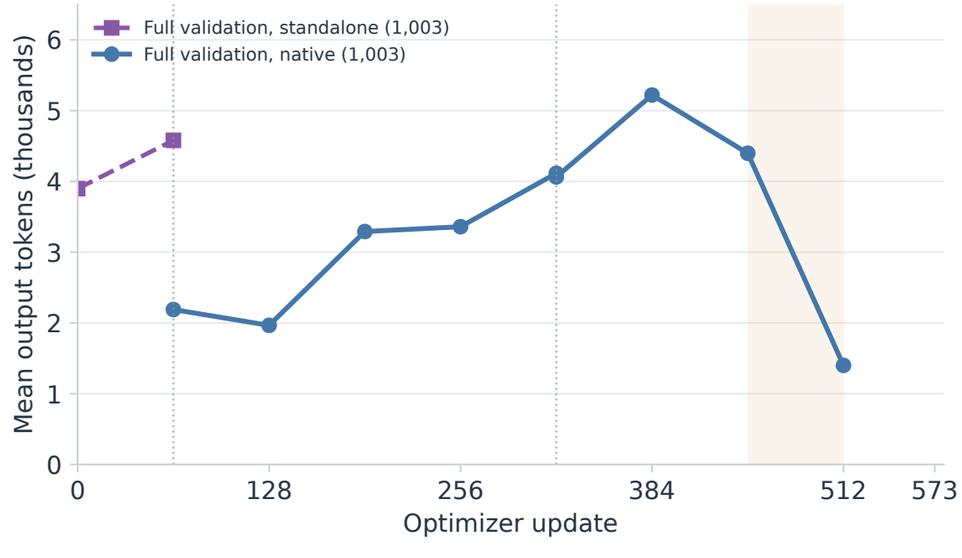
Different colors keep the evaluation protocols separate; they are not one matched accuracy curve.

Dotted vertical lines: scale-up at 64 and restart at 320 • shaded interval: 448–512

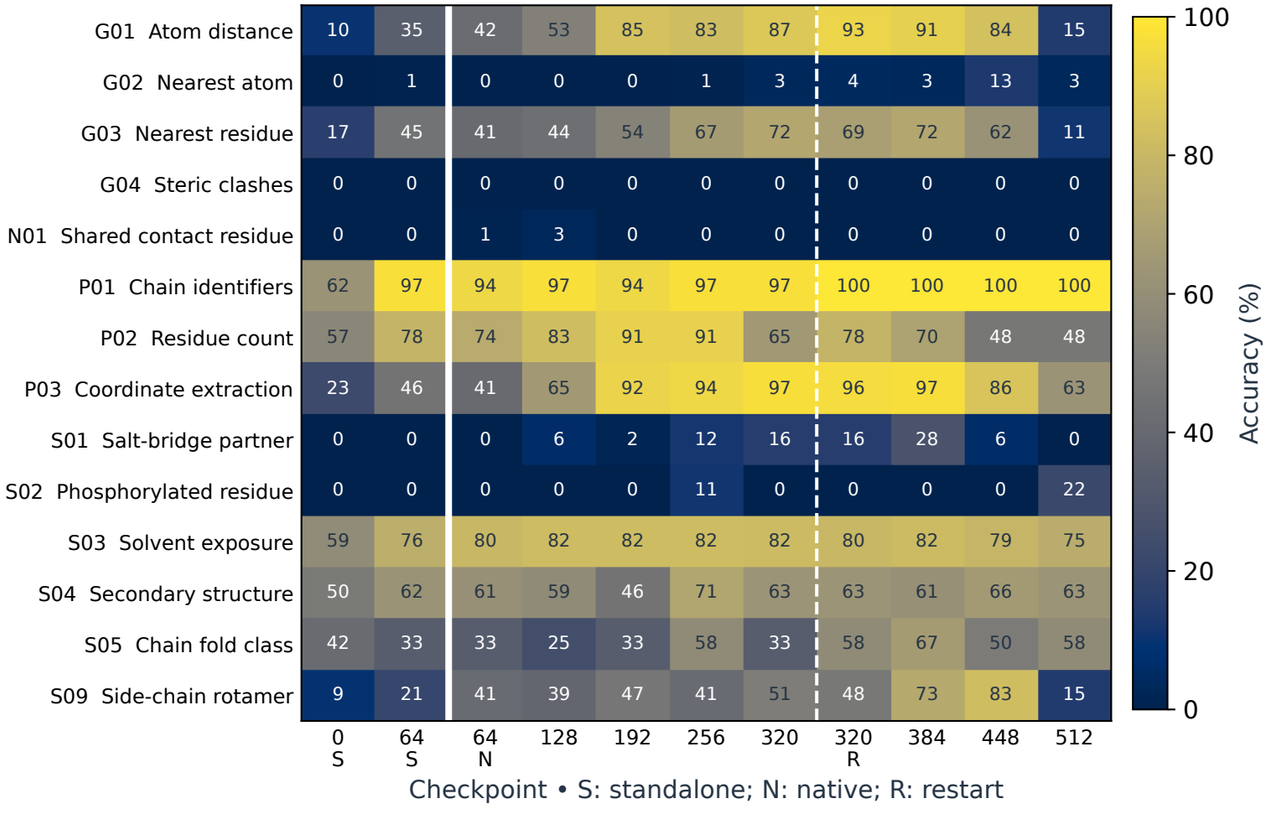
A Accuracy from the original model onward



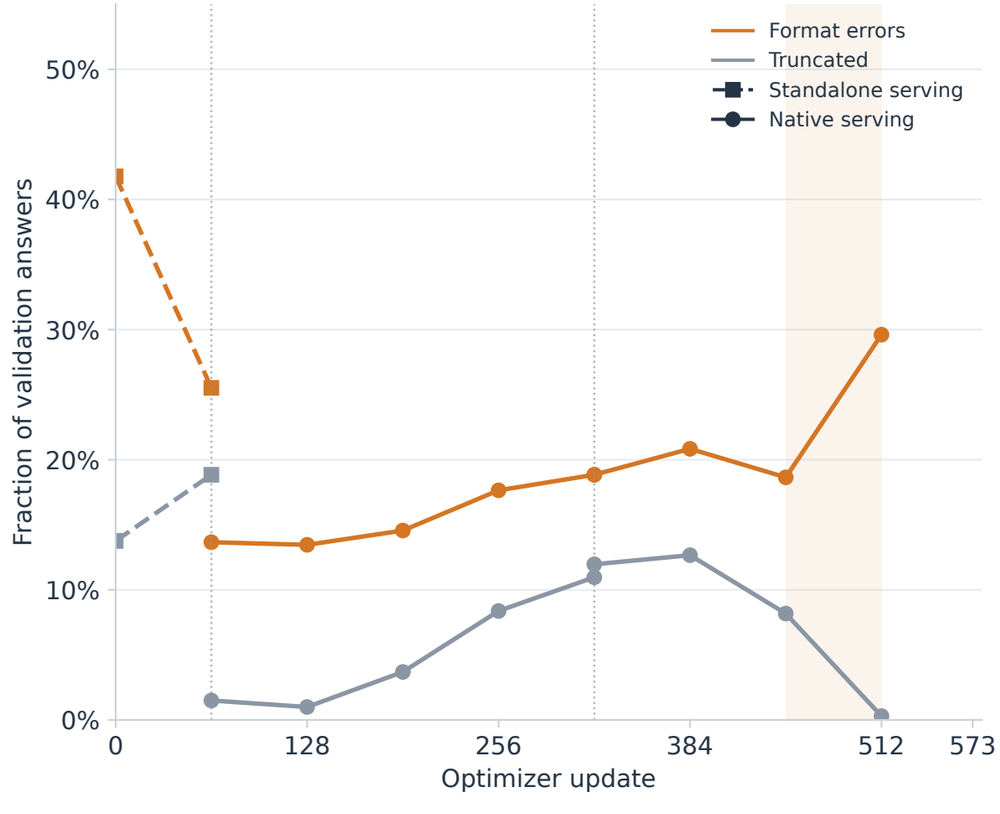
B Full-validation response length



C Every family, from step 0 (accuracy %)



D Format errors and truncation



Standalone full validation: step 0 = 230/1,003; step 64 = 378/1,003. Native full validation begins at step 64 = 401/1,003.
The two serving runtimes differ, so no line joins them at step 64. The 107-task pilot monitor is shown only in panel A.
Step 320 was evaluated twice around the restart (576 vs 580 correct). Latest full validation is at 512; no scores are extrapolated to later updates.
Format and truncation errors can overlap. Heatmap cells show rounded percentages; small families have few tasks.
